

# Chapter (3)

Prepared by

Karzan Abdulkareem Omar

# **Thermochemistry**

### Introduction

All chemical reaction is accompanied by energy changes, this change appear in the form of evolution or absorption of heat. This branch of chemistry which deals with study of energy changes accompanying chemical reactions is termed as "Thermochemistry".

Thermochemistry is based on the first law of thermodynamics. The energy change in chemical reactions is largely due to change of bond energy (i.e. it results from the breaking of bonds in reactants and formation of new bonds in products.

## Stander enthalpy change

As the enthalpy of reaction depends on temperature, a stander state is chosen to compare the enthalpies of reaction of different substances. A convenient stander state for a substance is the most stable under 1 atm and at the specified temperature (25°C or 298K).

For pure solids, liquids and ideal gases, the stander state corresponds to the state of the substance at 1 atm and specified temperature.

For the dissolved substances, the stander state of solute is that concentration which gives unit activity.

## Stander enthalpy change

The stander enthalpy of reaction at a temperature T and a pressure 1 atm is donated by

$$\Delta H^{\circ} = \sum \Delta H^{\circ}$$
 products -  $\sum \Delta H^{\circ}$  reactants.

Enthalpy for every element in its stander state is zero.

#### For example:

The enthalpy for formation of a mole of  $CO_2$  from its elements in the stander state is -393.5 kJ.mol<sup>-1</sup>.

$$C_{\text{graphite}} + O_2(g)$$
  $\longrightarrow$   $CO_2(g)$   $\Delta H^{\circ} = -393.5 \text{ kJ.mol}^{-1}$ 

The value of  $\Delta H^{\circ}$  is given as follows:

$$\Delta H^{\circ}_{298K} = H^{\circ} co_2 - [H^{\circ}o_2 + H^{\circ}c]$$

At stander state  $H^{\circ}o_{2} = H^{\circ}c = 0$ 

Hence, under these conditions

$$\Delta H^{\circ}_{298K} = H^{\circ} co_2 = -393.5 \text{ kJ}.$$

### Heat of reaction

A reaction which proceeds with the evolution (give out heat) of heat is referred to as an

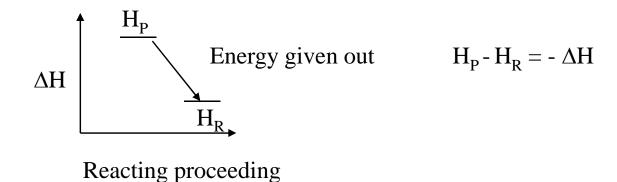

#### (a) exothermic reaction

In such reaction  $\mathbf{H}_{\mathbf{R}}\mathbf{0}\mathbf{H}_{\mathbf{P}}$ , so that  $\Delta \mathbf{H}$  is negative.

In exothermic reaction, the total internal energy of reactants is more than that of products and therefore the excess of internal energy will appear  $\Delta E$  is negative.

#### Example:

NaOH (s) + 
$$H_2O(l)$$
 NaOH (aq)

### Heat of reaction

#### (b) Endothermic reaction

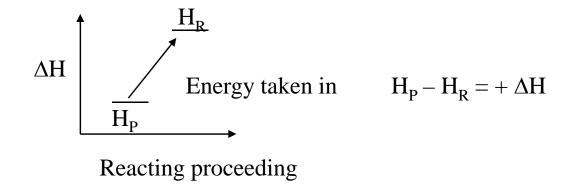

A reaction which proceeds with absorption of heat is referred to as an endothermic reaction.

In these reactions  $\mathbf{H}_{\mathbf{p}}\mathbf{OH}_{\mathbf{R}}$ , so that  $\Delta \mathbf{H}$  is positive.

In endothermic reaction, the total internal energy of products more than that of reactants and therefore the excess of internal energy will appear  $\Delta E$  is positive.

Example

$$NaHCO_3(s) + H_2O(l)$$
  $\longrightarrow$   $NaHCO_3(aq)$ 

### Relation between enthalpy and internal energy

Let consider a chemical reaction taking place at constant V and P, in such case w=0

$$\Delta U = q + w$$

$$\Delta U=q_V$$
 .....(1)

And when pressure constant

$$\Delta H = q_P \dots (2)$$

The quantities  $\Delta H$  and  $\Delta U$  are related to each other by the expression

$$\Delta H = \Delta U + P\Delta V \dots (3)$$

Substituting eq.(1) and (2) in eq.(3), we get

$$q_P = q_V + P\Delta V \dots (4)$$

This relationship can be simplified as follows:

For n moles of an ideal gas

$$PV = nRT .....(5)$$

### Relation between enthalpy and internal energy

Let  $n_1$  and  $n_2$  represent the number of moles of gaseous reactants and products, suppose  $n_2$  greater than  $n_1$   $\Delta n_g = n_2 - n_1$ . the corresponding increase in volume ( $\Delta V$ ).

We can write eq.(5) by substituting  $\Delta n_g$  as follows:

$$P\Delta V = \Delta n_g RT \dots (6)$$

Substituting eq.(6) in eq.(4), we get

$$\mathbf{q}_{\mathbf{P}} = \mathbf{q}_{\mathbf{V}} + \mathsf{U}\mathbf{n}_{\mathbf{g}}\mathbf{R}\mathbf{T}$$
 .....(7)

### Relation between enthalpy and internal energy

#### Example:

1. Reaction of the dissociation of ammonia into nitrogen and hydrogen

$$2NH_{3}(g) \longrightarrow N_{2}(g) + 3H_{2}(g)$$

$$2 \text{ moles} \qquad 1 \text{ mole} \qquad 3 \text{moles}$$

$$\Delta n_{g} = 4 - 2 = 2$$

$$q_{P} = q_{V} + 2RT$$

2. In the reaction involving combination of hydrogen and oxygen.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(1)$$
  
 $2 \text{ moles} \quad 1 \text{ mole} \quad 2 \text{ moles}$   
 $\Delta n_g = 3 - 2 = -1$   
 $q_P = q_V - RT$ 

### 1) Lavoisier and Laplace Law

This law was given by Lavoisier and Laplace in 1780 and state of law as follows"

"The amount of heat supplied to decompose a compound into its elements is equal to the heat of formation of that compound from its elements"

Means the heat of formation of compound is numerically equal to its heat of decomposition of a compound but of opposite sign.

The importance of this law is that thermochemical equations can be reversed.

For example:

$$C_2H_5OH + 3O_2 \longrightarrow 2CO_2 + 3H_2O \qquad \Delta H^\circ = -1366.95 \text{ kJ}.$$

Hence, by Lavoisier and Laplace's Law, we get

$$2CO_2 + 3H_2O \longrightarrow C_2H_5OH + 3O_2 \qquad \Delta H^\circ = + 1366.95 \text{ kJ}.$$

### 2) Hess's Law

State of Hess's Law as follows"

"The enthalpy change of a given chemical reaction is the same whether the process takes place in one or several steps".

Means heat of reaction does not depend upon the nature of intermediate products but depends only on the initial reactants and final products

For example: carbon dioxide may be produced by two processes which are:

### First procedure:

The burning of carbon can take place in a single step to form CO<sub>2</sub> with the enthalpy change which is equal to -393.5 kJ

$$C_{graphite} + O_2(g)$$
  $\longrightarrow$   $CO_2(g)$   $\Delta H^{\circ} = -393.5 \text{ kJ } \dots (1)$ 

### **Second procedure:**

It is possible to carry out above reaction in two steps.

First, all carbon can be converted into carbon monoxide

Second, carbon monoxide can be oxidized to carbon dioxide as follows:

$$CO(g) + 1/2O_2(g)$$
  $CO_2(g) \Delta H^{\circ} = -283.2 \text{ kJ .............(3)}$ 

On adding eq.(2) and (3), we get

$$C_{graphite} + O_2(g)$$
  $\longrightarrow$   $CO_2(g)$   $\Delta H^{\circ} = -393.7 \text{ kJ} \dots (4)$ 

From eq.(1) and (4), it shows that the enthalpy change in both the procedures is almost same, The small difference due to experimental error.

Application of Hess's law

Hess's law gives mathematical method of calculating:

- i) Heat of Reaction
- ii) Heat of Transition
- iii) Heat of formation
- iv) Lattice Energy of Crystal

# 3) The Kirchhoff Equation (Variation of Enthalpy of a Reaction with Temperature):

The enthalpy changes of any process, whether physical or chemical varies with temperature. The exact influence of temperature can be worked out as follows:

The enthalpy change for the reaction

is given by 
$$\Delta H = \sum \Delta H_{products} - \sum \Delta H_{reactants} = (cHC + dHD) - (aHA - bHB) ......(1)$$
  
Differentiating eq.(1) with respect to temperature, keeping pressure constant, we get 
$$[\partial(\Delta H)/\partial T]_{p} = c(\partial HC/\partial T)_{p} + d(\partial HD/\partial T)_{p} - a(\partial HA/\partial T)_{p} - b(\partial HB/\partial T)_{p} ......(2)$$

$$= cC_{p}C + dc_{p}D - aC_{p}A - bC_{p}B = \Delta C_{p}......(3)$$

Where,

 $\Delta C_P = Sum \text{ of heat capacities of products} - Sum \text{ of heat capacities of reactants}$ 

Eq.(3) is called Kirochhoff equation. It state that the variation of  $\Delta H$  of a reaction with temperature at constant pressure is equal to  $\Delta C_p$  of the system. We can get

$$d(\Delta H) = \Delta C_P dT \dots (4)$$

the temperature dependence of enthalpy of reaction at constant volume is given by

$$d(\Delta U) = \Delta C_V dT \dots (5)$$

if the temperature range of interest is small, eq.(4) and (5) can be easily integrated by assuming that heat capacities are independent of temperature. Accordingly

$$T_2$$
  $T_2$   $\int d(\Delta H) = \int \Delta C_P dT$  or  $\Delta H_2 - \Delta H_1 = \Delta C_P (T_2 - T_1)$   $T_1$   $T_1$ 

Similarly

$$T_2 \qquad T_2$$

$$\int d(\Delta U) = \int \Delta C_V dT \qquad \text{or} \qquad \Delta U_2 - \Delta U_1 = \Delta C_V (T_2 - T_1)$$

$$T_1 \qquad T_1$$

### Heat of Formation uhêf, uhf

Enthalpy change when one mole of a substance is formed from its elements in their stander states.  $\Delta H^{\circ}f$  value may be negative or positive.

$$\Delta H^{\circ} f = \sum \Delta H^{\circ} f$$
 products -  $\sum \Delta H^{\circ} f$  reactants

The heat formation of those compounds which cannot be determined experimentally can be calculated by Hess's Law.

For example:

Enthalpy for formation methane from carbon graphite and hydrogen cannot be found directly as no chemical reaction occur between graphite and hydrogen.

(i) 
$$C_{graphite} + 2H_2(g) \longrightarrow CH_4(g)$$

 $\Delta H$  for above reaction may be calculated by the help of the following reactions:

(ii) 
$$C_{\text{graphite}} + O_2(g) \longrightarrow CO_2(g) \Delta H = -393.5 \text{ kJ}$$

### Heat of Formation unef, unf

(iii) 
$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l) \Delta H = 2 \times (-285.9 \text{ kJ}) = -571.8 \text{ KJ}$$

(iv) 
$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(1)$$
  $\Delta H = -890.3 \text{ kJ}$ 

By adding eq.(ii) and (iii)

(ii) 
$$C_{graphite} + O_2(g) \longrightarrow CO_2(g) \Delta H = -393.5 \text{ kJ}$$

(iii) 
$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(1)$$
  $\Delta H = -571.8 \text{ KJ}$ 

(v) 
$$C_{\text{graphite}} + 2O_2(g) + 2H_2(g) \longrightarrow CO_2(g) + 2H_2O(l)$$
  $\Delta H = -965.3 \text{ kJ}$ 

On subtracting reversed eq.(iv) from eq.(v), we obtain

### Heat of Formation unef, unf

(v) 
$$C_{\text{graphite}} + 2O_2(g) + 2H_2(g) \longrightarrow CO_2(g) + 2H_2O(l)$$

$$\Delta H = -965.3 \text{ kJ}$$

(iv) 
$$CO_2(g) + 2H_2O(1) \longrightarrow CH_4(g) + 2O_2(g)$$
  $\Delta H = +890.3 \text{ kJ}$ 

$$\Delta H = +890.3 \text{ kJ}$$

$$C_{graphite} + 2H_2(g) \longrightarrow CH_4(g)$$

$$\Delta H = -965.3 + 890.3 = -75.0 \text{ kJ}$$

### Heat of Combustion UH.

Defined as the enthalpy change accompanying complete combustion of one mole of substance at 25°C and 1 atm pressure.

For example:

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(1)$$
  $\Delta H = -890.3 \text{ kJ}$ 

### Heat of Solution UH,

Defined as the amount of heat evolved or absorbed when one mole of solute dissolved in a sufficient amount of the solvent.

When the dissolution of solute in a solvent is accompanied by enthalpy change of system. If the heat is absorbed from the solution  $\Delta H_s$  is given a positive sign. If heat is evolved and given to solution  $\Delta H_s$  is given a negative sign.

The enthalpy change when one mole of a solute is dissolved in a solvent to give a solution of a specified concentration is called integral enthalpy of solution. It depends on number of mole of solvent.

## Heat of Solution UH,

Table of
Inegral Enthalpes of Solution in Water at 25°C

Substance	H2O moles	Heat of Solution kJ mole <sup>-1</sup>
HCl	200	- 72.9
HBr	200	- 83.3
NH <sub>3</sub>	200	- 35.3
NaCl	200	+5.3
K <sub>2</sub> SO <sub>4</sub>	400	+ 27.4
KCl	200	+ 18.6

It is clearly shown when the gases (HCl, HBr and NH<sub>3</sub>) dissolved in water,  $\Delta H$  has a negative value. (i.e. dissolution accompanied by evolution of heat. The dissolution of (KCl, NaCl and K<sub>2</sub>SO<sub>4</sub>) accompanied by absorbed of heat and their  $\Delta H$  has a positive value.

## Heat of solution UH,

#### For example:

One mole of potassium chloride is dissolved in 200 moles of water, heat absorbed is 18.58kJ. the integral heat of solution of KCl at this concentration, expressed by a thermochemical equation as follows:

$$KCl(s) + 200 H2O(l) \longrightarrow KCl(200 H2O)$$
  $\Delta H = + 18.58 kJ$ 

Similarly,

when 1 mole of gaseous hydrogen chloride dissolved in 50 moles of water, heat evolved is -72.2 kJ.

$$HCl(g) + 50 H_2O(1) \longrightarrow HCl(50 H2O)$$
  $\Delta H = -72.2 \text{ kJ}$ 

### Heat of Neutralization $\bigcup H_n$

Enthalpy of neutralization of one mole of a strong base (such as NaOH and KOH) by a strong acid (such as HCl, H2SO4 and HNO3) in dilute solution at 25°C and 1 atm pressure is called enthalpy of neutralization.

For example:

NaOH(aq) + HCl(aq) 
$$\longrightarrow$$
 NaCl(aq) + H<sub>2</sub>O(l)  $\Delta H = -57.3 \text{ kJ mole}^{-1}$   
KOH(aq) +1/2 H<sub>2</sub>SO<sub>4</sub>(aq)  $\longrightarrow$  KHSO<sub>4</sub>(aq) + H<sub>2</sub>O(l)  $\Delta H = -57.4 \text{ kJ mole}^{-1}$ 

The neutralization of hydrochloric acid by sodium hydroxide in dilute solutions when acid reacted with alkali salt formed are completely dissociated, can be represented by

$$H^{+} + Cl^{-} + Na^{+} + OH^{-} \longrightarrow Cl^{-} + Na^{+} + H_{2}O(l)$$
  $\Delta H = -57.32 \text{ kJ mole}^{-1}$  Or  $\Delta H = -57.32 \text{ kJ mole}^{-1}$   $\Delta H = -57.32 \text{ kJ mole}^{-1}$ 

The neutralization reaction is the same as it simply involves the combination of H<sup>+</sup> ions and OH<sup>-</sup> ions to form unionized H2O. the enthalpy of neutralization of all strong acid by a strong base and vice versa should be equal.

### Heat of Neutralization $\bigcup H_n$

If the acid or base is weak, the enthalpy of neutralization is different because the reaction now involves dissociation of weak acid or weak base.

#### For example:

The neutralization of acetic acid by sodium hydroxide, involves the dissociation of acid as well as the usual neutralization of H<sup>+</sup> and OH<sup>-</sup> ions. As represented below:

(i) CH<sub>3</sub>COOH (aq) = CH<sub>3</sub>COO<sup>-</sup> (aq) + H<sup>+</sup> (aq) 
$$\Delta H = y = 2.09 \text{ kJ mol}^{-1}$$

(ii) CH3COO<sup>-</sup> + H<sup>+</sup> + Na<sup>+</sup> + OH<sup>-</sup> = CH<sub>3</sub>COO<sup>-</sup> + Na<sup>+</sup> + H<sub>2</sub>O 
$$\Delta$$
H = - 57.32 kJ mol<sup>-1</sup>

by adding eq.(i) and eq.(ii), we get

(iii) CH3COOH + Na<sup>+</sup> + OH<sup>-</sup> 
$$\Longrightarrow$$
 COO<sup>-</sup> + Na<sup>+</sup>+ H<sub>2</sub>O  $\triangle$ H = - 55.23 = y +(- 57.23)

$$Y = 57.32 - 55.23 = +2.09 \text{ kJ mol}^{-1}$$

As H<sup>+</sup> ions neutralized by OH<sup>-</sup> ions furnished by the completely dissociated sodium hydroxide. More H<sup>+</sup> ions formed by the dissociation of acetic acid to re-establish the equilibrium. Thus both reactions proceed side by side till acetic acid is completely neutralized.

The enthalpy of neutralization of acetic acid by sodium hydroxide found to be  $\Delta H = -55.23$ 

$$\Delta H_{\text{acetic acid}} = +2.09 \text{ kJ mole}^{-1}$$

# Heat of Neutralization UH,

Table of
Standard Enthalpies of Neutralization of Strong Acid by Strong Base

Acid	Alkali	Enthalpy of Neutralization kJ mole <sup>-1</sup>
HCl	NaOH	- 57.32
HNO3	NaOH	- 57.28
HC1	КОН	- 57.45
HCl	LiOH	- 57.38

## Bond Energy

The bond energy of a particular type of bond in a molecule may be defined as the amount of energy required to dissociate or break one mole of that type present in the compound and separate the resulting atoms or radical from one another.

#### For example:

The bond energy of the H-H bond in H<sub>2</sub> is 433 kJ mol<sub>-1</sub>. it means that 433 kJ mol<sub>-1</sub> of energy is required to break or dissociate the H-H bond in one mole of hydrogen molecules.

# **Bond Energy**

Table of Enthalpies of formation of bonds viz, bond energy at 25°C

Bond	Enthalpy of formation (kJ mol <sup>-1</sup>
H – H	435.1
H – F	564.8
H – Cl	430.9
H – Br	368.2
O – O	138.1
O = O	493.7
O – H	464.4
C – H	416.2
C – O	351.4
C = O	711.3
C – C	347.3
C = C	615.0

# Application of bond Energy

#### 1) Determination of enthalpies of reactions

The bond energies can be used to determining enthalpies of reactions.

For example:

Determine the enthalpy of the reaction

$$H_2C=CH_2(g) + H_2(g)$$
  $\longrightarrow$   $H_3C-CH_3(g)$   $\Delta H = ?$ 

In this reaction, the four C-H bonds of  $C_2H_4$  remain unaffected. A double bond breaks in ethylene and an H-H bond breaks in  $H_2$ , therefore one C-C and two C-H bonds are formed in  $C_2H_6$ .

$$\Delta H = -\Delta H_{C-C} - 2\Delta HC - H + \Delta HC = C + \Delta H_{H-H}$$
  
 $\Delta H = -347.3 - 832.4 + 615 + 435.1 = -129.6 \text{ kJ mol}^{-1}$ 

# Application of bond Energy

#### 2) Determination of enthalpies of formation of compound

For example: formation of acetone

$$3C(g) + 6H(g) + O(g) \longrightarrow CH_3-CO-CH_3$$

- I) Breaking 3H-H bonds to give six atoms of H, breaking of half O-O bond to give one atom of O and sublimation of 3C(s) to give three atoms of C(g).
- II) Formation of two C-C bonds, six C-H bonds and one C=O bond.

$$\Delta Hf = -2\Delta H_{C-C} - 6\Delta HC - H - \Delta HC = O + 3\Delta H_{H-H} + 1/2\Delta H_{O-O} + 3\Delta H_{C(s)} \longrightarrow_{C(g)}$$

$$= (-2 \times 347.3 - 6 \times 416.2 - 711.3) + (3 \times 435.1 + 1/2 \times 138.1 + 3 \times 719.6)$$

$$= -369.95 \text{ kJ mol}^{-1}$$

### Application of bond Energy

#### 3) Determination of resonance energy

For example:

$$C_6H_6 \longrightarrow 6C + 6H$$

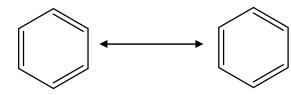

Benzene ring consists of three single and three double bonds (Kekule's structure), calculate the dissociation energy comes out as follows:

$$\Delta H_{f} = 3\Delta H_{C-C} + 3\Delta H_{C=C} + 6\Delta H_{c-H}$$

$$= 3 \times 347.3 + 3 \times 615.0 + 6 \times 416.2 = 5384.1 \text{ kJ mol}^{-1}$$

The experimental value is known to be 5535.1 kJ mol<sup>-1</sup> but actual energy required for the dissociation of benzene is 151 kJ mol<sup>-1</sup> more than the calculate value. This clearly shows actual structure of benzene is more stable than Kekule structure by 151 kJ mol<sup>-1</sup>

The actual structure represented as follows:

## Factors effecting on Bond Energy

#### (a) Length of the bond

It is found the greater the bond length between the two nuclei of the two atoms forming

the bond, the smaller is bond energy.

Type of bond	H - H	Cl - Cl	I - I
Bond length	0.74	1.25	2.7
Bond energy	433.1	330.5	151.2

#### (b) Bond polarity

Greater is the strength of the dipole along the bond and higher is the bond energy.

## Factors effecting on Bond Energy

#### (c) Unsaturation

It observe that with the increase in number of covalent bonds between atoms, increase in the bond energy

Bond	Energy in kJ/mol
C – C	347.3
C = C	615.0
c <b></b> ≡c	811.7

#### (d) Resonance effect

The bond energy per bond depends the amount of resonance.

#### (e) Overlap of orbital

The bond energy depends upon the s character which is determined by extent of overlap of orbital of the combining atoms.

# **Examples on Thermochemistry**

## Example (1)

One mole of naphthalene was burnt in oxygen gas at constant volume to give carbon dioxide gas and liquid water at 25°C. the heat evolved was found to be 5138.8 kJ. Calculate the enthalpy of reaction at constant pressure.

## Example (2)

The enthalpy of combustion of glucose  $C_2O_{12}O_6(s)$  is -2816 kJ mol<sup>-1</sup> at 25°C. calculate  $\Delta H^{\circ}f$  ( $C_2O_{12}O_6(s)$ ) . The  $\Delta H^{\circ}f$  value for CO2 (g) and  $H_2O(l)$  are -393.5 and -285.9 kJ mol<sup>-1</sup>.

### Example (3)

The heat evolved on dissolving  $CuSO_4$  (s) in water is 86.6 kJ mol<sup>-1</sup>. If  $\Delta H^{\circ}f$   $Cu^{+2}$  is 64.4 kJ mol<sup>-1</sup>, what  $\Delta H^{\circ}f$  ( $SO_4^{-2}$ ). If  $\Delta H^{\circ}f$   $CuSO_4$  (s) is - 770 kJ mol<sup>-1</sup>

## Example (4)

Cyanamid was subjected to combustion at constant volume and the heat evolved was found to be 742.7 kJ mol<sup>-1</sup> at 25 $^{\circ}$ C. calculate  $q_v$ .

### Example (5)

Calculate the enthalpy of formation OH<sup>-</sup> ions at 25°C from the following thermochemical equations:

$$H_2O(1)$$
  $\longrightarrow$   $H^+(aq) + OH^-(aq)$   $\Delta H^\circ = 57.3 \text{ kJ mol}^{-1}$   
 $H_2(g) + 1/2O_2$   $\longrightarrow$   $H_2O(1)$   $\Delta H^\circ = -285.9 \text{ kJ mol}^{-1}$ 

### Example (6)

The enthalpy of reaction for the formation of ammonia according to reaction:

 $N_2 + 3H_2$  2NH<sub>3</sub> at 27°C was found to be – 91.94 kJ. What will be the enthalpy of reaction at 50°C?

The molar heat capacities at constant pressure and 27°C for N2,H2 and NH3 are 28.45, 28.32 and 37.07 joules.

## Example (7)

### H.w

Calculate the enthalpy change at 125°C for the reaction.

$$N_2 + 3H_2 \longrightarrow 2NH_3$$
  $\Delta H = -92.41 \text{ kJ mol}^{-1}$ 

The molar capacities (in J.K<sup>-1</sup>. mol<sup>-1</sup>) for the various gases involved in the reaction vary with temperature as following:

$$C_P(N_2) = 27.26 + 5.23 \times 10^{-3} \text{ T} - 4.18 \times 10^{-9} \text{ T}^2$$

$$C_p(H_2) = 29.02 - 8.35 \times 10^{-4} \text{ T} + 20.80 \times 10^{-7} \text{ T}^2$$

$$C_p(NH_3) = 25.86 + 32.94 \times 10^{-4} \text{ T} + 30.42 \times 10^{-7} \text{ T}^2$$

### Example (8)

How much heat is required to raise the temperature of one mole of oxygen from 300 K to 1300 K at constant pressure?

$$C_p = 6.095 + 3.253 \times 10^{-3} \text{ T} - 1.017 \times 10^{-6} \text{ T}^2$$

### Example (9)

Heats of neutralization of  $NH_4OH$  and HF are -51.5 and 68.6kJ mol<sup>-1</sup>. Calculate heat of dissociation.

## Example (10)

Calculate the bond enthalpy for a C-O band in methanol from the following data:

i) 
$$C(s) + 2H_2(g) + 1/2O_2$$

 $CH_3OH(g)$ 

$$\Delta H^{\circ} = -200 \text{ kJ mol}^{-1}$$

C(g)

$$\Delta H^{\circ} = +716.8 \text{ kJ mol}^{-1}$$

iii) 
$$2H_2(g)$$

4H(g)

$$\Delta H^{\circ} = + 872.0 \text{ kJ mol}^{-1}$$

iv) 
$$1/2O_2(g)$$

O(g)

$$\Delta H^{\circ} = + 249.0 \text{ kJ mol}^{-1}$$

the bond enthalpy for C-H and O-H bonds are 413 and 463.6 kJ mol<sup>-1</sup>.

### Example (11)

The bond enthalpy of  $H_2(g)$  is 436 kJ mol<sup>-1</sup> and that of  $N_2(g)$  is 941.3 kJ mol<sup>-1</sup>. Calculate the average bond enthalpy and N-H in ammonia  $\Delta H^{\circ}f = -46.0$  kJ mol<sup>-1</sup>

i) 
$$N_2(g) \longrightarrow 2N(g)$$
  $\Delta H^{\circ} = 941.3 \text{ kJ mol}^{-1}$ 

ii) 
$$H_2(g) \longrightarrow 2H(g)$$
  $\Delta H^{\circ} = 436.0 \text{ kJ mol}^{-1}$ 

iii) 
$$1/2N_2(g) + 3/24H_2(g) \longrightarrow NH_3(g)$$
  $\Delta H^{\circ} = -46.0 \text{ kJ mol}^{-1}$
